

Carbohydrates

Learning Objectives

- Define the following terms: monosaccharide, disaccharide, polysaccharide, carbohydrate
- Describe the relationship between monosaccharide and carbohydrates.

Carbohydrates

Living things use carbohydrates as their main source of energy.

Monosaccharide

Single Sugar Molecules

glucose

galactose

fructose

GLUCOSE

GALACTOSE

FRUCTOSE

Disaccharide

Two Sugar Molecules

SUCROSE

Sucrose
(glucose and fructose)

LACTOSE

Lactose
(galactose and glucose)

MALTOSE

Maltose
(glucose and glucose)

Polysaccharide

Many Sugar Molecules

Plants make cellulose, a tough, flexible fiber that gives plants much of their strength and rigidity.

Glycogen

Many animals store excess sugar in a polysaccharide called glycogen (animal starch).

Glycosidic Bond

Carbohydrates are made by linking monosaccharides using a glycosidic bond.

Function of Carbohydrates

Provides Energy:

Carbohydrates are the most important energy source for your body.

Energy Storage:

Plants - store energy in sugars and starch.

Animals - Store energy in glycogen.

Support and Structure:

Plants - cellulose provides support

Why do many athletes “carb-up” before a big event?
